Outline

1. Introduction
2. Data and Variables
3. Methods
   - Measuring Socioeconomic Inequalities
   - Decomposition of Socioeconomic Inequalities
4. Results
   - Descriptive Results
   - Socioeconomic Inequalities in Daily ESHS
   - Decomposition Results
5. Summary and Conclusion
   - Summary
   - Conclusion
Tobacco use is a major global health challenge that accounts for 6 million deaths each year (10 percent of all adult deaths) (WHO 2014).

The detrimental health effects of exposure to environmental tobacco smoke are a particularly substantial public health challenge in low-and-middle-income countries (LMICs).

Approximately 80 per cent of smokers live in LMICs worldwide (WHO 2014).
Children may be particularly vulnerable to the adverse effects of ESHS because:

1. They have lesser control over their indoor environments and experience greater exposure to secondhand smoke compared to adults (US Department of Health and Human Services 2006).
2. They are still developing physiologically, children may be particularly sensitive to ESHS (Sleiman et al. 2010).
ESHS increases the risk of developing several health problems in children.

**Examples**

Asthma, sudden infant death syndrome (SIDS), respiratory track infections (e.g. pneumonia and bronchitis) and middle ear infections (US Department of Health and Human Services 2006).

- ESHS has also indirect effects on children’s health because household expenditures on tobacco products compete with spending on food, health care, and other basic resources (Coughlin 1997).
Children living in socioeconomically disadvantaged households are at higher risk of ESHS because their parents or other household members are more likely to smoke (Sims et al. 2010). In addition, there are fewer smoking restrictions in their homes (Phillips et al. 2007).
Some recent work (e.g. Gartner & Hall 2012; Yi et al. 2012; Moore et al. 2011) has analysed socioeconomic gradients in ESHS among children in higher-income context.

The relation between socioeconomic status (SES) and ESHS among children in LMICs, however, remains poorly understood.

This study, thus, aims to first, provide a comprehensive analysis of socioeconomic-related inequality in ESHS among children (aged 0-5) in 26 LMICs, and second, decompose the overall wealth-based inequality in daily ESHS in each country into inequality within and between urban and rural areas.
Data

- 26 Demographic Health Surveys (DHSs): 2010-14
- Sample size: 313,857 children aged 0-5
- The DHS surveys collect comparable information concerning a wide range of topics, with a special focus on maternal and child health.
Main Variables

- **Daily exposure to secondhand smoke (ESHS):** it is determined using a variable in DHSs that describes frequency of household members smoke inside the house.

- **Wealth Index:** an indicator of individual-level socioeconomic status (SES)

- **GDP per capita (PPP, current international $)** and **adult (+15) literacy rate:** indicators of country-level SES.
We used the concentration index approach to measure wealth-related inequalities in each country and in urban and rural areas in each country.
The Relative Concentration index ($RC$)

- The index is **positive** if outcome is concentrated among the higher SES children, and **negative** if it is concentrated among the lower SES children.

- The range of the index is from -1 to +1, with a value of zero indicating “perfect equality”.

![Graph showing the Relative Concentration Curve and Line of Equality]

Cumulative % of children exposed to secondhand smoke

Hajizadeh and Nandi

Socioeconomic gradient in daily ESHS in LMICs
The Relative Concentration Index (RC)

- The RC index computed using the “convenient regression” approach suggested by Kakwani et al. (1997):

\[ 2\sigma^2_R \left( \frac{Y_i}{\mu} \right) = \alpha + \beta R_i + \varepsilon_i, \quad (1) \]

- where \( Y_i \) is children \( i \)'s daily ESHS,
- \( \mu \) is the mean of the daily ESHS for the total sample,
- \( R_i = i/N \) is the fractional rank of individual \( i \) in the distribution \((i = 1 \text{ and } N \text{ for the poorest and wealthiest individual, respectively})\), and
- \( \sigma^2_R \) indexes the variance of fractional rank.
- The ordinary least squares estimate of \( \beta \) represents the RC.

- As daily ESHS is binary, we normalized the RC by multiplying the calculated index by \( 1/1-\mu \) (Wagstaff, 2005).
The Absolute Concentration Index \((AC)\)

- \(AC = \mu \times RC\)
- The \(AC\) ranges from \(-\mu\) to \(+\mu\), with value zero indicating “perfect equality”.

Hajizadeh and Nandi Socioeconomic gradient in daily ESHS in LMICs
We decomposed the RC and AC indices in order to calculate the contributions of inequality within and between urban and rural areas.
If $RC_{tc}$ represents the relative concentration of ESHS in the population as a whole in a country, $c$, it can be decomposed as (Lambert & Aronson 1993):

$$RC_{tc} = RC_{bc} + \sum_j \gamma_j RC_{jc} + R,$$

(2)

- where $RC_{bc}$ is relative inequality between regions (rural-urban),
- $\gamma_j$ is the product of the region $j$’s share of the daily ESHS and its share of the total population,
- $RC_{jc}$ is the relative concentration of daily ESHS in the region $j$, and
- $R$ is a reranking term.
Decomposition of the Normalized $RC$ and $AC$

- Decomposition of the normalized $RC_{tc}$:

$$ RC_{tc}/1-\mu = RC_{bc}/1-\mu + \sum_j \gamma_j R C_{jc}/1-\mu + R/1-\mu, \quad (3) $$

- Decomposition of the normalized $AC_{tc}$:

$$ AC_{tc}/1-\mu = AC_{bc}/1-\mu + \sum_j \gamma_j A C_{jc}/1-\mu + \mu R/1-\mu, \quad (4) $$
Prevalence (%) of daily ESHS among children (0-5) in 26 LMICs
In the majority of countries more than 20 per cent of children aged 0-5 were exposed to second-hand smoke on a daily basis at home. While in countries such as Honduras, Tajikistan and Ethiopia less than 10 per cent of children were exposed to secondhand smoke, this figure was greater than 60 per cent in Indonesia, Jordan and Armenia. Children’s daily ESHS was higher in rural areas compared to urban areas in the majority of the countries.
In the majority of countries more than 20 per cent of children aged 0-5 were exposed to second-hand smoke on a daily basis at home.

While in countries such as Honduras, Tajikistan and Ethiopia less than 10 per cent of children were exposed to secondhand smoke, this figure was greater than 60 per cent in Indonesia, Jordan and Armenia.

Children’s daily ESHS was higher in rural areas compared to urban areas in the majority of the countries.

Cross-country correlations country level socioeconomic indicators and daily ESHS

![Graphs showing the relationship between daily ESHS prevalence and Log GDP per capita and Adult (15+) literacy rate.](attachment:image.png)
The estimated RC and AC demonstrated that daily ESHS was concentrated among poorer children in almost all countries (RC, median=-0.174 and AC, median=-0.037).

The concentration of daily ESHS among poorer children was greater in urban relative to rural areas.
The estimated RC and AC demonstrated that daily ESHS was concentrated among poorer children in almost all countries (RC, median=-0.174 and AC, median=-0.037).

The concentration of daily ESHS among poorer children was greater in urban relative to rural areas.

We found negative socioeconomic gradient in all but two countries – Mali and Tajikistan – of the 26 LMICs.

The concentration of ESHS among the poor children was greater in urban compared to rural areas.

The decomposition analysis suggest that:

- **Within areas inequality** is the main determinant of socioeconomic inequality at the national level in most of the countries (median=44 per cent).
- The **median contribution of inequality of daily ESHS between areas** to the overall measures of socioeconomic inequality was 29 per cent.
1. Self-reported measure of daily ESHS could be an issue in our analysis if under-reporting was associated with SES.

2. As ESHS is bounded, the minimum and maximum of the RC (AC) are not $-\mu$ (-1) and $\mu$ (1). There was much lively debate as to how to overcome this issue in health economics literature (e.g. Wagstaff 2009, Erreygers 2009, Kjellsson & Gerdtham 2013a; Kjellsson & Gerdtham 2013b; Allanson & Petrie 2013).
Limitations

1. Self-reported measure of daily ESHS could be an issue in our analysis if under-reporting was associated with SES.

2. As ESHS is bounded, the minimum and maximum of the RC (AC) are not $-\mu$ (-1) and $\mu$ (1). There was much lively debate as to how to overcome this issue in health economics literature (e.g. Wagstaff 2009, Erreygers 2009, Kjellsson & Gerdtham 2013a; Kjellsson & Gerdtham 2013b; Allanson & Petrie 2013).
Children from rural and socioeconomically disadvantaged households (particularly those living in urban areas) are more likely to experience daily ESHS at home.

Thus, special attention should be devoted to address ESHS among these groups because socioeconomic disparities in ESHS might lead to socioeconomic disparities in tobacco-related health problems among the children over the life-course.
Children from rural and socioeconomic disadvantaged households (particularly those living in urban areas) are more likely to experience daily ESHS at home.

Thus, special attention should be devoted to address ESHS among these groups because socioeconomic disparities in ESHS might lead to socioeconomic disparities in tobacco-related health problems among the children over the life-course.
